ABSTRACT

Background: Chemotherapy induced nausea and vomiting are the main undesired side effect that distress around 70% to 80% of cancer patients. Ginger is often advocated as beneficial for nausea and vomiting, whether the herb is truly efficacious for this condition or not it is still a matter of debate. Objective: This scoping review is conducted to assess the effect of ginger usage on nausea and vomiting induced by chemotherapy amongst adult patients with cancer.

Methodology: Databases searched include MEDLINE, CINHAELE, PubMed and Google scholar for related articles between 2012 to 2019 was performed. After extensive review,188 studies were retrieved from the databases and only 15 studies found eligible according to applied inclusion and exclusion criteria. (14 randomized controlled trails, 1 pilot study) with a total of 1974 patients with different cancer types receiving emetogenic chemotherapy.

Results: The majority of available evidence demonstrates that ginger is an effective, inexpensive and safe treatment for nausea and vomiting.

Conclusion: Ginger supplementation can be potentially efficient effects on the patients who receives chemotherapy-induced nausea and vomiting. The results of this scoping review provide significant suggestions for further research using standardized ginger products and reflective larger sample sizes to confirm the efficacy of ginger extract supplement and optimal dosing regimens.

KEYWORDS: Cancer Patients; Chemotherapy induced nausea, Vomiting; Ginger; Ginger extract

INTRODUCTION

Due to of the intrinsic emetogenicity of chemotherapeutic agents Chemotherapy related induced nausea and vomiting is a major issue distressful for cancer patients undergoing treatment Bossi et al. [1]. Its prevalence is reported between 54% and 96% Sheikh [2]. Chemotherapy-induced nausea and vomiting (CINV) among patients with cancer impacts treatment outcomes and quality of life Adel [3]. As a result, nausea and vomiting caused by chemotherapy are due to 50% to 60% of the symptoms of chemotherapy patients suffering from protein food deprivation as a result of failure to meet nutritional requirements, which further jeopardizes medication results Rapoport [4]. In addition to having a destructive experience, CINV may cause consequently affect the immune system, performance status and electrolyte imbalance Ansari et al. [5]. Despite the decrease in CINV by using various classes of antiemetic agents, CINV occurs in 60-80% of chemotherapy patients Ansari et al. [5].

In addition, different approaches, including pharmaceutical or complementary treatments, are used to monitor CINV. Herbal
therapy is the most commonly complementary therapies used among the people Sanaati [6]. Based on a World Health Organization (WHO) report, about 80% of the world population stratify herbal compounds now Sanaati [6]. Ginger (Zingiber officinale) is a conventional remedy in many cultures for nausea and vomiting and has been investigated for use in motion sickness, morning sickness and postoperative nausea Palaty [7].

Ginger on the U.S. Food and Drug Administration classified in the safe list of herb and included it in many pharmacopeias Western countries Lete [8]. The exact mechanism remains indistinct; however, the effects of "gingerol and shogaol" compounds on various chemotherapy-induced nausea and vomiting processes are known to have beneficial effects Marx et al. [9]. Ginger has beneficial effects on muscarinic and histaminergic receptors through its antagonistic effect; its capacity to control gastric emptying and gastrointestinal motility; and its function in reducing oxidative stress and inflammation Marx et al. [9].

**SEARCH STRATEGIES**

This literature guided by Arksey and O'Malley stated of five stages methodology Arksey H 2005. First, the PICOT question was identified “In patients with cancer treated by chemotherapy, how does the used ginger, compared with no use ginger, affect the experience of nausea and vomit induced by chemotherapy?” To guide the search process in the database. Then, to identify articles relevant to this scoping review, which focus on the effect of ginger use on reducing nausea and emesis, searching was initiated in an electronic database between October and November 2019. Recent articles were collected between 2012-2019 to identify the recent studies conducted under the same objective under specific inclusion and exclusion criteria. Finally, a thematic framework sated to guide and sorting of existing literature and review matrix was completed to collating, summarizing, and reporting the results (Appendix 1).

**KEYWORDS**

Combination of key ward was used which include: 'ginger or ginger extract', 'chemotherapy induced nausea and vomiting' and 'cancer patients'.

**SEARCH ENGINES**

The electronic searching included extensive searching in databases from the Database of Cumulative Index of Nursing and Allied Health Literature “CINHAL”, Midline, PubMed, and grey literature also conducted using Google scholar for more evidence. through examined for population, intervention, comparison, the outcome of the study.

**INCLUSION AND EXCLUSION CRITERIA**

Inclusion and Exclusion Criteria were developed according to our aim of study to identify the most appropriate articles to answer PICOT question which included the following:

**Inclusion Criteria**

a) Studies that are available in English language only.

b) Studies address only cancer who receive chemotherapy.

c) Studies was conducted in adult population 18 years or more.

d) Published studies conducted in the last 7 years between 2012-2019.

e) Only quantitative research included.

f) Articles that study ginger or ginger extract with patient treated with chemotherapy induced nausea and vomiting with different types of cancer and measured effect to reduce nausea and vomiting.

**Exclusion Criteria**

a) Studies in other language than English language

b) Articles that are not relevant to the topic such as articles address effect in other of chemotherapy as radiation therapy.

c) Studies that included infant and children in population.

d) Articles was before 2012.

**ARTICLES RETRIEVED AND SCREENING PROCESS**

To identify literature screen PRISMA was used. (Preferred Reporting Items for Systematic Reviews and Meta-Analysis). PRISMA contain four phase flow diagrams explained in Figure
1. At first, a total of 188 studies were found through search databases. Plus, 5 records identified through other sources (gray literature). After duplicates removed 9 articles were eliminated. The search was narrowed to 184 articles according to the inclusion and exclusion criteria were established. Then the remaining 29 articles, titles, abstract and full texts were screened manually by the researchers and only relevant articles were retrieved. Finally, 15 full-text articles were included, 7 articles not relevant outcome were eliminated. 1 pediatric article excluded. Also, 6 review articles were eliminating. We included in our search published articles only quantitative methods are screens.

FINDING AND RESULTS

The finding of our Scope Review was identified by thematic analysis into categories in three themes, the first theme is discussing the reduction effect of ginger on chemotherapy induced nausea and vomiting while the second theme is discussing the conflict effect. The last theme discusses the non-reduction effect. Themes are illustrated in Table 2 below.

Theme 1: Reduction Effect on CINV

Ginger had been used for centuries for gastrointestinal disturbance. Chemotherapy-induced (CINV) can have a negative impact on patients’ quality-of-life. There is evidence that suggests taken ginger with standard antiemetic drugs, ginger may add additional reducing or eliminating of nausea and vomiting pre and intra chemotherapy cycles.

Konmun et al. [10]; Alexander [11]; Sanaati [6]; Tahir [12]; Ryan et al. [13]; Yekta et al. [14] conducted similar studies and established the use of ginger along with antiemetic medication to reduce nausea and vomiting experience in a cancer patient who is receiving chemotherapy.

According to Konmun et al. [10] who conduct a randomized double-blind placebo-controlled in Thailand. The aim was to study the effect of one of bioactive ginger extract (6-gingerol) on a client who receives chemotherapy-induced nausea (CINV). The effect of ginger was tested in at least 3 cycles of chemotherapy in the multicycle interval that included an eighty-eight patient with different cancers types participant were assigned into two groups, the intervention group took ginger extract, referred to as 6-gingerol 10 mg capsules while the control group take placebo capsule to contain microcrystalline cellulose three days prior of the first day of
chemotherapy and continued to 12 weeks of treatment. The result illustrated that as compared to placebo, all patients in interventional groups of ginger experiment experienced significantly reduced acute and delayed nausea and emesis experiences ($p=0.003$) in addition to ondansetron, metoclopramide, and dexamethasone use in both groups.

Another study was conducted by Alexander [11] investigated the effect of Indian ginger tea on nausea and emesis induced by chemotherapy among cancer patients in Bharat Hospital and Institute of Oncology at Mysore India. The sample consisted of 60 patients, 30 patients allocated in each experimental and control group. The experimental group ($n=30$) had oral administration of Indian ginger tea from the 1st day of the chemotherapy cycle, while the control group was not given Indian ginger tea. The result indicated that administration of Indian ginger tea was reducing nausea and vomiting effectively as the independent $t$ values were statistically significant at 0.05 level of significance.

Other study was done in turkey that support similar result conducted through a double blind randomized controlled trials study to evaluate the effect of ginger on nausea and vomiting induced by chemotherapy. All sample in the study 60 patients received standard antiemetic drug. Patients in the intervention group consumed powdered ginger added to yogurt, 30 minutes before chemotherapy administration while control group provided standard care. The study tests the mean score of nausea severity, frequency of vomiting and retching episodes. According to the result of this comparison, the study emphasis that nausea severity and the frequency of vomiting episodes were significantly decrease in the group who receive ginger than in the control group ($p > 0.05$). Despite this, the variation in of retching episodes was not statistically significant ($p > 0.05$) between the intervention and control groups Arslan [15].

Furthermore, Alparslan et al. [16] Non- randomized controlled study (NRS). The study was conducted to evaluate the efficacy of ginger on chemotherapy-induced nausea and emesis on cancer patients who received chemotherapy in the hematology clinic. Over time, the study group was consisting of 15 in the intervention group and 30 in the control group. Whereas the intervention group received ginger tablets (800 mg) compared with the control group received antiemetic drugs. The current study proposed that ginger is effective in lowering chemotherapy-induced nausea and emesis.

According to a randomized cross-over experimental study published by Montazeri et al. [17] aimed to evaluate ginger use among cancerous under chemotherapy-induced nausea and vomiting. The participants of this trial were selected from oncology patients’ presence in haematology departments in many university hospitals in Iran. The researcher was allocated participants into two groups A and B with specific interventional or placebo regimes to evaluate the effects of these two regimes on the patients who treated with emetogenic chemotherapy according to inclusion criteria to in role to the plan. The interventional group was a standard antiemetic drug additional to 4 ginger capsules, two of the capsules taken 30 minutes prior to chemotherapy administration, the other two capsules were given after 6 hours chemotherapy session. The placebo group was received a routine antiemetic therapy with 4 placebo capsules. Then, participant of these two groups was crossed over to receive the other regime. The severity of nausea and vomiting assessed using korting tools. The result of the study identified that participants who receiving ginger showed a significant reduction in frequency and less severe form of nausea and vomiting compared to the participant who received a placebo.

These results were consistent with the Sanaati [6] randomized, double-blind, and clinical trial research to locate the impact of ginger and chamomile capsules on nausea and vomiting in chemotherapy on 65 women with breast cancer. The women Participating in this experiment were divided into two groups. Ginger and chamomile and one control group, a routine antiemetic regimen consisting of dexamethasone, metoclopramide, and aprepitant (DMA) capsule were consumed. Consequently, the results showed that Ginger and chamomile had a significant effect in reducing the frequency of vomiting, there being no significant difference between the ginger and chamomile groups. Moreover, unlike chamomile, the level of nausea was greatly affected by ginger.

Ryan et al. [13] performed a randomized, double-blinded, placebo-controlled, multicenter trial in the United States to determine the effects of ginger in controlling chemotherapy-induced nausea (CIN). The study included 744 patients (576 patients included in the final analysis) with different cancer who were randomly assigned into four groups the first group given a placebo, while the other three groups received different concentration ginger doses 0.5 g, 1.0 g, and 1.5 g of capsules ginger beside received the standard antiemetic a 5-hydroxytryptamine (3) receptor antagonist plus dexamethasone. Patients started to take 3 ginger capsules or placebo, three days prior to chemotherapy cycles for 6 days. The result illustrated that the different ginger doses (0.5 g, 1.0 g, or 1.5 g) reduced the severity of acute nausea ($p = 0.003$) compared to the placebo. The researchers reported that the largest reduction in the intensity of nausea was taking place with 0.5 g and 1.0 g of the ginger capsule ($p = 0.017$ and $p = 0.036$, respectively).

Recent research has been published by Tahir [12]. Who conduct a randomized control trial to find out the effect of using ginger as a prophylactic antiemetic in reducing the delayed chemotherapy-induced vomiting, additionally to standard antiemetic therapy for patients who receiving emetogenic chemotherapy? The study was conducted in Jinnah Hospital, Lahore, Pakistan, with a total study sample of 90 patient, who divided into two groups, intervention group how received a cap of 500 mg ginger orally TID, 3 days prior to chemotherapy and 3 days after chemotherapy and olanzapine as a based standard antiemetic regimen. The other group consists of 45 patients who received only olanzapine as standard antiemetic therapy. The results of the study did respond significantly to the addition of ginger capsules. Only 35.6% of patients had vomiting after chemotherapy as compared to 62% of patients in the standard therapy group ($p$-value 0.006).

Yekta et al. [14] conducted a related study under similar
concern by using double-blind randomized experiment trial, study
was accomplished on eighty female who diagnosed with breast
carcinoma and on single-day chemotherapy cycle in Imam Khomeini
Hospital in Iran, the patients were selected through convenience
sampling and allocated randomly into two groups intervention and
placebo-control groups.

The intervention members received capsules of ginger powder
250 mg called (Zintoma) that contained (250 mg dry powdered
ginger root that was prepared with 10:1 ratio of ethanol 50% and
ginger root and included 5.38 mg (2.15%) 6-gingerol, 1.8 mg
(0.72%) 8-gingerol, 4.19 mg (1.78%) 10-gingerol, and 0.92 mg
(0.37%) 6-shogaol, all of these components are active form of
ginger extract. The placebo group received 250 mg starch-filled
capsules, both of these groups received four times a day with a
six-hour interval, the total dose was (1000 grams per day) for six
contiguous days, 3 days prior initiate chemotherapy sessions in
addition to antiemetic including granisetron hydrochloride, and
dexamethasone use in each group. A daily self-report assessment
tool was used to evaluate the ginger effect. The result shows that
there is a significantly lower vomiting rate in the ginger group and
placebo-control groups throughout of chemotherapy session. Also,
the only reported adverse event was heartburn effect experience
notice.

Theme 2: Partial Effects on Nausea or Vomiting

One study conducted to measure the efficacy of ginger in the
controlling of nausea and vomiting induced by chemotherapy
among cancer patients shown conflicting results, means that there
is a ginger effect on one symptom and nothing on another symptom.

According to a pilot, randomized clinical trial study carried
out by Panahi et al. purposed to assess the efficacy of ginger for
acute and delayed CINV. Among 100 women newly diagnosed
with advanced stages breast cancer who received chemotherapy
treatment, including docetaxel, epirubicin, and cyclophosphamide,
and those patients who randomly assigned to ginger group (1.5 g/d
in 3 separated doses every 8 hours intended for 4 days) in addition
to standard antiemetic regimen, while control group received
standard antiemetic regimen alone. The result display that taking
ginger with antiemetic drugs helped to reduce chemotherapy-
induced nausea. However, there is no significant effect of ginger on
the frequency of vomiting 2013.

Theme 3: Non-Reduction Effect on CINV

Based on our findings through literature reviewing of relevant
issue, there are four recent studies that evaluated participant
experiences who received ginger extract through the cycles of
chemotherapy, the result revealed that using of ginger did not add
any significant effect on nausea and vomiting reduction.

Bosi et al. [1] conducted a randomized, double-blind, placebo-
controlled, multicenter study in patients in six Italian oncology
centers, planned to receive two cycles or more of nightly emetogenic
chemotherapy with a high dose of cisplatin (>50 mg/m²), in
treatment duration range from 42-56 days. Patients were randomly
distributed into two groups, the intervention group received ginger
capsules extract 160 mg/day (Gingerols: 16 mg and Shogaol 1.12
mg combined dose of bioactive compounds) or placebo in addition
to the prophylactic antiemetic medication for CINV, starting
from the first day and fifth day of cisplatin administration. It was
conducted on 251 patients, 121 patients received ginger extract
capsule and while the control group was 123. Lung and head and
neck cancer were the most represented tumors types. The result
shows that there are no significant differences between two groups
throughout the two cycles of chemotherapy, no difference was a
notice in emesis nausea assessment scores between the ginger and
placebo group Bossi et al. [1].

In contrast, Thamlikitkul et al. [18]. A double-blind, crossover
study RCT in Thailand to investigate the effects of ginger for
chemotherapy-induced nausea and vomiting (CINV) prophylaxis in
female patient with cancer patients who received adriamycin and
cyclophosphamide (AC) chemotherapy. The study suggests that
ginger capsule, was safe, at a dose of 1 g/day for 5 days, starting
on the first day of chemotherapy, but indicate that no significant
difference compared with control group in word of reducing nausea
and vomiting severity in female patients with breast cancer who
receiving AC chemotherapy.

Li [19] conducted randomized, double-blind, placebo-
controlled clinical trial of 140 patients with lung cancer receiving
cisplatin-based regimens was enrolled and devoted to receiving
either ginger root powder or a placebo. However, the result showed
no the difference is obvious was spotted between the ginger and
control groups in the lowering of the incidence and severity of
nausea and vomiting (P > .05).

A Prospective study conducted in Namazi Hospital affiliated
with Shiraz University of Medical Sciences, Shiraz, Iran aimed
to assess the efficacy of ginger in control of nausea and vomiting
induced by chemotherapy in female patients who were newly
diagnosed with breast cancer for the first 3 chemotherapy cycles,
119 females were randomized to intervention group who receive
500 mg ginger powder, twice a day for 3 days and control group
who received placebo. In all sessions, the result illustrates that no
significant differences between the ginger group and the control
group Ansari et al. [5].

Lua [20] studied the effects of ginger inhalation as aromatherapy
on chemotherapy-induced nausea and vomiting for breast cancer
women. A 100 mm visual analog assessment scale (VAS) was
used. They conduct this study through single-blind, randomized,
controlled, cross-over study at two clinics of oncology in the East
Coast of Peninsular in Malaysia. Sixty patients divided into two equal
groups, group 1 inhaled “ginger fragrance oil” on their first cycle of
therapy as (placebo) group, then they inhaled “essential oil” on the
followed chemotherapy cycle. While Group 2 were initially inhaled
“essential oil” on their first cycle of chemotherapy, then were given
“ginger fragrance oil” for the followed treatment cycle. The result
showed that there was no significant difference in the mean of VAS
nausea scores between the two groups (P=0.183). Likewise, ginger
aromatherapy treatment not significantly has an effect on
the reduction of vomiting (P=0.59). The only study was found ginger
were not ingested it was used as inhaled aromatherapy.

LIMITATIONS

In this scope review most of the recent studies show insufficient
evidence to support ginger usage in a patient were treated with CINV.
Discrepancies in the result of studies reflect varies of emetogenic ty
of chemotherapy used through the studies and antiemetic regimens
as well as cancer stage or types and participant condition in study
duration. In addition, substantial clinical heterogeneity was
introduced through different ginger active substance composition,
dose frequency regimens, and administration techniques as well
as using different assessment tools. Furthermore, this review
was limited by the small recent numbers of available studies that
reported the outcomes of interest. Most of our literature found internationally while no studies were conducted in the Middle East or in Saudi Arabia [21,22].

STUDY IMPLICATION

Nursing Practice

Cancer and its treatment often cause physical and psychological problems that impact the quality of patient life. The administration of ginger tea as a simple and less expensive intervention can be adopted to decrease nausea and emesis induced by chemotherapy.

Nursing Research

Ginger has been used for a long time as a traditional herbal antiemetic. We recommended for future studies on the efficacy of ginger as an antiemetic in chemotherapy-induced nausea and vomiting to advance nursing practice. This includes examining the effects of the ginger administer more than once, for an extended period, bigger sample sizes, which include different cancer types.

Nursing Education

We recommend training sessions on complementary alternative therapies to improve the knowledge and skills of nurses and make them more competent to provide high standard quality care for cancer patients who are receiving chemotherapy. Furthermore, we suggest adding the alternative and complementary therapy to the curriculum of the nursing university to prepare the nursing student to research, analyze, and integrate the evidence-based practice in their practice.

CONCLUSION

Ginger supplementation can potentially efficiently effect on the patient who receives chemotherapy-induced vomiting. In this scoping review literature, there were a variation of ginger dose used in experiment, different form of ginger extract, sample size and different assessment tool used through the experiment reflect the variation in the result.

Lua, Salihah, Mazlan (2015) Malaysia

To assess the efficacy of inhaled ginger aromatherapy on nausea, vomiting and health-related quality of life (HRQol) in chemotherapy breast cancer patients.

Single-blind, controlled, randomized cross-over study.

Sixty female patients with breast cancer on Chemotherapy.

Patients in Group 1 was provided with ginger fragrance oil (placebo) on their first chemotherapy course, followed by ginger essential oil on the next chemotherapy course.

Group 2 were first supplied with ginger essential oil on their first chemotherapy course, and then were given placebo (ginger fragrance oil) for the next treatment course.

- There was no significant mean difference of VAS nausea scores between ginger essential oil and ginger fragrance oil [F(1, 58) = 1.82, P = 0.183] indicating that there was no significant effect of aromatherapy on nausea severity.
- Similarly, there was no significant effect of aromatherapy treatment on vomiting [F(1,58) = 0.29, P = 0.594].

Arslan M, Ozdemir L (2015) Turkey

This experimental randomized, controlled trial was done to assess the effect of ginger on chemotherapy-related nausea and vomiting.

RCT

60 females with breast cancer, currently receiving chemotherapy with adjuvant anthracycline.

Receiving palonosetron-aprepitant antiemetic treatment, being at least in the second cycle of chemotherapy and having experienced chemotherapy-induced nausea.

Sachet (powdered ginger root on yogurt).

Standard care.

The current study demonstrated that ginger administration was effective in decreasing the severity of acute and delayed nausea in women with breast cancer receiving anthracycline-based chemotherapy.

Montazeri, Raei, Ghanbari, Dadgari, Montazeri AS, Hamidzadeh A (2013) Iran

The objective of this study was to evaluate the efficacy of complimentary ginger among cancer patients experiencing nausea and vomiting.

Randomized cross-over clinical trial.

During the first cycle was 44. In the second cycle, were 31 patients.

Group A regime was a routine antiemetic drugs along with 4 ginger capsules. Then, subjects of the study were crossed over to receive the other regime.

Group B regime was a routine antiemetic along with 4 placebo capsules. Then, subjects of the study were crossed over to receive the other regime.

- The severity of the nausea at end of 24 hours in people who received regime A rather than placebo reduced by %27.3 in the first cycle and the severity of the nausea at end of 24 hours in people who received regime B rather than placebo reduced by %24.1. in the second cycle. The severity of vomiting at end of 24 hours, in the first cycle of measurement for group A is 4.7 less than (placebo).
- The severity of vomiting at end of 24 hours, in the second cycle of measurement for group B reduced by % 8.3 in comparison to the placebo.
